Abstract

Fishes-good protein diet source, have been classified since old times so as to know their whereabouts and their exciting facts as water dwellers. Fishes belonging to different taxa are widely studied so as to gain a proper knowledge about them, as with increasing demand and simultaneous intensification of fish resources serving along with human exploitation, it has become a serious concern about the dwindling existence of the fishes.

The present investigation was to study the ichthyo-diversity pertaining to the state of Manipur wherein there were Lake and Rivers that would get an insight to the presence of the varied types of fishes available in the concerned region. The endemic species population was also found and its abundance trend was brought out. The study also coincided with the knowing of the diversity of the fishes as well as the present scenario of the same.

Keywords: Barak, Mizoram, Manipur, fish diversity, IUCN

Introduction

Fishes are *unselfish cold-blooded* water dwellers serving as rich protein diet to mankind and maintaining aquatic ecological balance. They constitute more than half of the living vertebrates recognised (Nelson, 2006) ^[50]. The number of valid fish species is nearly 31,000, and 500 new species being constantly added in every year. This increase in the number of fish species in the recent years has been attributed to the increasing resource surveys or expeditions in new areas and depths which were not accessible earlier, modern approaches to taxonomy and cataloguing of the resources (Eschmeyer *et al.*, 2010) ^[51]. Fish constitutes almost half the total number of vertebrates. Of the 39,000 species of vertebrates recognised the world over, 21,723 are fish species of which 8,411 species are freshwater, while 11,650 are marine (Jayaram, 1999) ^[19]. Fishes are one of the important elements in the health and economy of many countries as they have been a staple item of diet of many people in the world. They constitute slightly more than half of the total number approximately 54,711 recognized living vertebrate species; there are descriptions of estimated 27,977 valid species of fishes.

The fishes are one of the main exploitable resources of the aquatic ecosystems that provide a cheap source of protein. Fishes are one of the important elements in the economy of many nations as they have been a stable item in the diet of many people (Kar *et al.*, c2005) ^[53]. Adequate protection of ecosystems is a necessary requirement for survival of all species and proper care is needed to overcome anthropogenic stresses. In the case of commercial species, rational exploitation is a pre-requisite for sustainability of the resources. The study of fishes is devoted to a branch of zoology called Ichthyology wherein detailed fish study is done.

India ranks ninth in terms of freshwater mega biodiversity hotspots of the world (Mittermeier and Mittermeier, 1997) ^[54]. In India, there are 2500 species of fishes of which 930 live in freshwater and 1570 species live in marine water (Kar, 2003) ^[52]. The Indian fish fauna is divided into two classes, viz., Chondrichthyes and Osteichthyes. The Chondrichthyes are represented by 131 species under 67 genera, 28 families and 10 Orders in the Indian region.

The annual average landings of the Indian Chondrichthyes is 33,442 tons, of which, 15,537 tons come from the east coast and 17,605 tons come from the west coast and the rest come from the Andaman and Nicobar, and Lakshadweep Islands.

The Indian Osteichthyes are represented by 2,415 species belonging to 902 genera, 226 families and 30 orders, of which, five families, notably the family Parapsilorhynchidae are endemic to India. These small hillstream fishes include a single genus, viz., *Parapsilorhynchus* which contains 3 species. They occur in the Western Ghats, Satpura Mountains and the Bailadila range in Madhya Pradesh only. Further, the fishes of the family Psilorhynchidae with the only genus *Psilorhynchus* are also endemic to the Indian region. Other fishes endemic to India include the genus *Olytra* and the species *Horaichthys setnai* belonging to the families Olyridae and Horaichthyidae respectively. The latter occur from the Gulf of Kutch to Trivandrum coast. The endemic fish families form 2.21 percent of the total bony fish families of the Indian region. 223 endemic fish species are found in India, representing 8.75 percent of the total fish species known from the Indian region and 128 monotypic genera of fishes found in India, representing 13.20 percent of the genera of fishes known from the Indian region.

About 22000 species of fishes have been recorded in the world; of which, about 11% are found in Indian waters. Out of the 2200 species so far listed, 73 (3.32%) belong to the cold freshwater regime, 544 (24.73%) to the warm fresh waters domain, 143 (6.50%) to the brackish waters and 1440 (65.45%) to the marine ecosystem.

Manipur (Latitude 23.80° N to 25.68°N and Longitude 93.03°E to 94.78°E) a state in the northeast corner of India has a subtropical climate with average temperature ranging from 0° C-32°C and annual rainfall as 1657.6 mm. The state has a total geographical area of 22,356 sq.km and is characterized by three River systems namely-Manipur, Chindwin, River Barak. The state is drained by various streams which belong to the Manipur River and its tributaries along with other smaller streams and associated Lakes forming the water resources of the valley. A catchment of 6,332sq.km constituting about 28.4% area of the state discharge maximum quantity of water through Manipur River system during monsoon months (May-September) and frequently inundate the land along their bank. The state of Manipur with its Lakes like the Loktak, Awangsoi, Utra and also the Rivers-Imphal River, Nambul River, Lokchao River, Thoubal River, Khujailok River is a paradise of beauty with its water bodies enriching the scenario. Variety of fishes are available in the hilly streams, Lakes, and Rivers of the valley starting from the Cypriniformes family upto the Cichlidae family. There are catfishes, live fishes, ornamental fishes and also endemic species like *Osteobrama belangeri* that add to the biodiversity of the ichthyodiversity of the state.

Loktak is a Ramsar site with abundance of varied fish species. Awangsoi Lake and Utra Lake are also having huge Perciformes and Cypriniformes species. Principal River Imphal and others like Thoubal, Nambul in the southern part of the state has varied fish species composition. Also Rivers like Khujailok, Lokchao houses some near threatened and vulnerable species. *Osteobrama belangeri*, *Oreochromis mossambica*, *Glyptothorax manipurensis*, *Schistura manipurensis* are some such species.

The proper identification of a specimen in a museum aids to the fact that it is taxonomically studied and identified and thus is categorized as per norms of IUCN or standard literature.

Then the diversity of the species in the concerned geographical area can be ascertained and also the status of the fish can be very well known. This would help in the conservation of the species as that is the main aim of taxonomic study.

Objective of the study

The objectives of the present work is to study the fishes of Manipur, Barak and Mizoram drainage preserved in AUS fish museum taxonomically and to know the diversity index of the preserved fishes. Also the current status of the preserved fishes was ascertained according to IUCN Red List.

Review of Literature

There is an urgent need to undertake a thorough taxonomic review of several genera and species of freshwater fishes. Fishes constitute more than half of the living vertebrates recognised (Nelson, 2006) ^[50]. The number of valid fish species is nearly 31,000 and 500 new species being constantly added in every year. This increase in the number of fish species in the recent years has been attributed to the increasing resource surveys/expeditions in new areas and depths which were not accessible earlier, modern approaches to taxonomy and cataloguing of the resources (Eschmeyer *et al.*, 2010) ^[51]. Distribution and taxonomy of freshwater fish have been studied in India over the years (Raj 1916, Motwani and Saigal 1974, Barman 1994, Easa and Shaji 1997, Kumar *et al.* 1999, and Rema devi *et al.* 1999) ^[55, 56, 57, 58, 59]. Although, there are several studies on the native fish fauna in general, very few studies have been done.

North East India is considered as one of the hot spots of freshwater fish biodiversity in the world (Xottelat and Whitten, 1996). It is a well recognised fact that there has been drastic reduction in abundance of the freshwater fishes in this region due to destruction of the habitat, overexploitation and other anthropogenic effects. Review of literature indicates that only limited information is available on fish germplasm resources of North East India with special reference to its potential as cultivable, sport and ornamental fishes. There has been a wide variation in the number of fishes reported from this region ranging from 172 (Ghosh and Lipton, 1952) to 267 (Sen, 2000) ^[61, 62]. Also detailed drainage wise distribution, seasonal abundance, endemism and preferred microhabitats have not been critically examined.

NBFGR, Lucknow in 1992 had identified nine endemic fishes of North East region as most 'threatened'. These are *Ompok pabda*, *O. pabo*, *Labeo dyocheilus*, *Sernipiotus semrpiotis*, *Olyra longicaudata*, *Psibiorhynchus homaioptera*, *Noemacheilus elongatus*, *Balitora brucci* and *Barbus dukai*. Sinha (1994) ^[63] has listed 13 species as threatened from North East. Yadav and Chandra (1994) ^[64] reported total disappearance of some species from the landing from Brahmaputra since 1975 onwards. *Labeo dyocheilus* and *Mystus vittatus* have not been reported by them since 1977 from River Brahmaputra. Recent report (Biswas and Barua, 2001) ^[65] show dominance of undersized fishes in fish landings in North Eastern states especially from Brahmaputra River system.

Of the 587 freshwater fishes reported in India, 320 were assessed in a six-day Conservation Assessment and Management Plan (CAMP) workshop under the Biodiversity Conservation Prioritization workshop jointly organized by NBFGR and Zoo Outreach organization based on International Union for Conservation of Nature and Natural

Resources criteria in 1997. Of the 320 species assessed, about 105 were from North Eastern region of these five are categorized as: critically endangered (CR), one extinct En the wild (EW), 31 are endangered (En), 46 are vulnerable (Vu), 42 are lower risk near threatened (LR-nt), eight are Lower risk least concern (LR-lc) and three are data deficient (DD). Of the North East species, 513 species were not covered in CAMP evaluation. Based on IUGN Red-list criteria and available information, the experts at the CAMP workshop had concluded that one species *Osteobrama belangeri* (Valenciennes) as extinct in the wild. Later interactions with other fishery experts from North East indicated that *O. belangeri* is not extinct from all locations from North East and the earlier CAMP assessment was based on local extinction of some populations of this species. In a very recent survey conducted by Loktak Development Authority, Manipur *Osteobrama belangeri* was collected from Loktak Lake (Singh, 1999). The five species under CR category are *Garra litanensis*, *G. manipumsis*, *Aborichthys garoensis*, *Lepidocephalus goalparensis* and *Pangasius pangasius*. Of these, three species are endemic to this region. Thirty one species categorized as endangered are also facing a high risk of extinction in the wild in the near future. Eleven of the endangered species are endemic. Forty six species are assessed under vulnerable (Vu) category which indicates that they are also facing a high risk in the future.

Immense works on taxonomy have been done by Hamilton (1822) [12]; Shaw and Shebbeare (1937); Hora (1921a, b, 1930, 1937, 1939, 1940, 1943, 1951, 1953); Misra (1959); Menon (1974 [34], 1999) [36]; Dey (1973); Jayaram (1981, 1999) [19, 16]; Sen (1982, 1985); Talwar and Jhingran (1991) [46]; Nath and Dey (1999, 2000); Dey and Kar (1989a, b, c, 1990); Kar and Dey (1986, 2000, 2002); Kar and Barbhuiya (200a, a, 2004); Kar *et al.* (2002a, b, c, 2003, 2004); Kar (1984, 1990, 2003a, b, 2004, 2005a, b, c, d, e). The recent studies on deep-sea fish taxonomy from Indian EEZ include the documentation and redescription of *Glyptothidium oceanium* from the west coast (Kurup *et al.*, 2008), deep-sea eel *Bassozetus robustus* (Cubelio *et al.*, 2009a), *Dicrolene nigricaudis* (Cubelio *et al.*, 2009b), deep-sea sharks like

Hexanchus griseus, *Deania profundorum*, *Etmopterus pusillus* by Akhilesh *et al.* (2010), *Symphysanodon xanthopterygion* by Anderson and Bineesh (2011). Kar *et al.* reported immense works on Lakes and Rivers of Manipur valley with respect to the ichthyofaunal characters as well as taxonomic studies.

Materials and Methodology

Duration of the project work: The Project work span was from February, 2014 to April, 2014. The preserved fish specimens were re-identified and then kept in 10% formaldehyde solution.

The identification, systematic list and classification of the preserved fishes were done following standard literature of Jayaram (1998, 2010) [18], and Kar, (2007), while nomenclature was after Fish-Base (<http://www.fishbase.org>). The morphometrics and meristics calculation were based on APHA (1998, 2006). The status of the preserved fish species in the studied Rivers and wetlands was preliminarily ascertained after Menon (1994) [35] and Molur & Walker (1998). The taxonomic study of identifying the specimens was done following literature and these studies were also aided by certain materials such as scale, point needles, forceps, dividers, electronic balance and thus the species was specimen was identified upto species level.

The diversity indices of the fishes was calculated after Shannon-Weaver index of diversity (Shannon-Weaver, 1949 [43]; Wolda, 1983). The status of preserved fishes was confirmed after IUCN (1994) and also the vulnerability was assessed after Fish Base.

Result

The taxonomic study of the fishes preserved in the museum was done following appropriate methodology and thus the total number of species was studied. The following tables (TABLE I, TABLE II, TABLE III) represents the diversity (including Order and Family) of the collected fish specimen from different wetlands, Rivers of Manipur, Barak and Mizoram Drainage. While TABLE IV represents the IUCN Red list and Vulnerability status of those collected specimen.

Table 1: Fishes of Manipur

Sl.	Wetland/River name	Order	Family
1	Nambal	Cypriniformes	Cyprinidae, Clariidae, Cobitidae

Graph (3 & 4): Represents the species richness and fish species diversity index of Mizoram drainage

Graph (5 & 6): Represents the species richness and fish species diversity index of Manipur drainage

Discussion

Ichthyological survey conducted since 1996, in the north bank tributaries of River Barak (*viz.* Jiri, Chiri, Madhura and Jatinga) and south bank tributaries (*viz.* Sonai, Rukni, Ghagra, Dhaleswari and Katakahal) revealed the occurrence of 47 fish species (belonging to 39 genera, 14 families and 6 orders) and 44 species (belonging to 34 genera, 14 families and 6 orders) respectively till date.

The ichthyological survey conducted in the upstream regions of River Tuirial, Tuirini, Tuivai and Tlawang in Mizoram, joining the Barak drainage, revealed the occurrence of 18 species of fish (belonging to 17 genera, 18 families and 3 orders) till date. Moreover, collection of ichthyofauna from the River Chhimtuipui (Kolodyne or Kaladan) in Mizoram bordering Myanmar and from River Mat joining River Chhimtuipui in Mizoram, revealed the occurrence of 12 species of fishes (belonging to 10 genera, 4 families and 3 orders).

From the above study, a total of 195 different species of fishes found to be observed in from the Barak Drainage System belonging to different Order and Family (Table II), and 51 species of fishes found to observed in different wetlands of the Barak Drainage System (Table II), while a total of 26 different species are found from Mizoram (Table III). Where in Barak Drainage System have 8 orders of fishes as Cypriniformes 79 species, Perciformes 38 species, Siluriformes 48 species, Beloniformes 13 species, Clupiformes 4 species, Osteoglossiformes 5 species, Synbranchiformes 7 species, and Tetraodontiformes 1 species each respectively. And in Mizoram there are 6 orders of fishes observed, in which Cypriniformes have 10 species, followed

by Siluriformes 7 species, and Perciformes 6 species, Beloniformes, Osteoglossiformes, Synbranchiformes have 1 species, each respectively.

As a whole a total 487 no. of fish species were recorded, analysed, and identified, the Shannon Diversity Index (H) of the whole mesuem specimen were found to be ranging from -0.05 to -0.12 (Graph 2, 4 & 6). The Shannon diversity index (H) is commonly used to characterization of species diversity in a community, it also accounts for the both abundance and evenness of the species present. The resulting products is summed across the species, where equability assumes a value between 0 and 1 with 1 being complete evenness.

The detailed taxonomic study of the preserved fish species done during the project term revealed many aspects that can be helpful for not only knowing the species identities but also helpful in knowing their current status and their conservation measures. The fishes collected from Nambul, Lokchao, Thoubal, Imphal River and and also from three Lake namely, Loktak, Awangsoi, Utra were identified upto specific level with the help of standard literature and it was found that fish species belonged to the order-Osteoglossiformes, Cypriniformes, Perciformes, Siluriformes. Also diversity in terms of families observed such as Notopteridae, Cyprinidae, Cobitidae, Channidae was also observed. The most number of species were observed in order Cypriniformes (45spp.) followed by Perciformes (33spp.), then Siluriformes (4spp.)

Conclusion

In the light of global decline in biodiversity, it has become essentially urgent to gain a thorough idea about the taxonomic perspectives of the fish species so as to have a detail idea of

the classification practices as well as to know the diversity indices of the different species and their present status that would help in their proper conservation. Manipur being a beautiful state with hydrographical scenario harbours Lakes and Rivers with rich species diversity, but the deterioration of the water conditions has led to a decrease in the number of species concerned as the number of vulnerable species and threatened have comparatively increased.

With context to my present study, it can be concluded that the total species studied diversely belong to order CYPRINIFORMES and PERCIFORMES, and to the families CYPRINIDAE and CHANNIDAE largely. The further study of the present status revealed facts about existence of endemic species *Osteobrama belangeri* and its dwindling scenario. Positive measures like more detailed study of the fish species on taxonomic perspectives has become inevitable for the existence of the species as because with the advent of environmental hazards it has become a need for the hour to preserve the specimens in the museum and to gather extensive and sound knowledge of their status and diversity as it would help in preventing their extinction, thereby lending a penny to the mere global diversity and ichthyodiversity which is at stake these days. However, further study is still required for the accomplishment of the aforesaid perspectives that would differentially aid in fish resource conservation and prioritization.
